Answer: BCE. To establish an electric circuit, charge must be moved from low energy to high energy. Once at high energy, the charge spontaneously flows through the conducting wires and other conducting elements of the circuit back down to the low energy terminal. A battery's role is to supply the energy which is required to move the charge from the - terminal to the + terminal of the battery.

A circuit is a closed path or loop around which an electric current flows. Most circuits have three parts: an energy source, one or more loads, and conductors (wires) that connect the two. A circuit may also have a switch that can be open, which stops the flow of current, or closed, which allows the current to flow.

The Electric Current in a circuit flows from positive to negative while electrons flow from negative to positive. So when the switch is on the path is complete and electricity passes through enabling the bulb to light up, while when the switch is not on, there is a break in the flow of electricity and the bulb does not light up.

Brief Introduction to Circuits | electricaleasy.com

A DC circuit is necessary for DC electricity to exist. DC circuits may be in series, parallel or a combination. The electricity moving through a wire or other conductor consists of its voltage (V), current (I) and resistance (R). Voltage is potential energy, current is the amount of electrons flowing through the wire, and resistance is the friction force on the electron flow.
