A shear wall is simply a cantilevered diaphragm to

which load is applied at the top of the wall, and is transmitted out along the bottom of the wall. This creates a potential for overturning which must be accounted for, and any overturning force is typically resisted by hold-downs or tie-downs, at each end of the shear element.

An engineer will optimize a shear wall's design to meet the specific demands of a house, which will dictate details like nail size and nailing schedule, hardware placement, and blocking size and orientation. LATERAL: The primary lateral force from an earthquake or high-wind event causes simultaneous uplift, compression, and sliding forces.

Shear Walls & Diaphragms
When designing a building for lateral loads such as those generated by wind or earthquakes, a design engineer may have several alternatives. Lateral loads may be transferred to the foundation via braced frames or rigid frames, diagonal rods or "X" bracing, including let-in bracing in the ease of wood frame construction, or other methods.
